#### Background

### Background

- Ubiquitous location based services affect people's daily life deeply.
  - Baidu Map, Uber ...
- Mobility data is now collected routinely at a very large scale.
- The data is usually generated from heterogeneous data sources
  - Different devices, mobile apps, LBS providers ...
- Identifying the trajectories of the same user across different sources:
  - Fundamental ingredient of the mobility data integration.
  - Improve the quality and density of the data.

Q: Is it possible to identify the users across heterogeneous data sources?

### Problem Statement

- Trajectory  $T = \{p_1, p_2, \dots, p_{|T|}\}$ 
  - Sequence of spatio-temporal points in temporal order
- Mobility data set D
  - Collection of trajectories from a single data source.
- Matching trajectories
  - Trajectories  $T_A$  and  $T_B$  which are collected from different sources
  - $T_A$  and  $T_B$  are generated by the same user
  - Then,  $T_B$  is the matching trajectory of  $T_A$
- Objective:
  - Given: Data sets  $D_A$  and  $D_B$  (collected from two different sources)
  - Our goal: Find the matching trajectory in  $D_B$  for each  $T_A \in D_A$ .

### Related Work

- User trajectories similarity search <sup>1</sup>
  - Retrieve a subset of trajectories with similar patterns
- Human mobility uniqueness<sup>2</sup>
  - Each individual has her/his own mobility pattern
  - People tend to visit the places where they often visited in the past.

\*Few prior work studies the case under heterogeneous data sources.

<sup>&</sup>lt;sup>1</sup>Li et al. SIGSPATIAL 2008, Chen et al. SIGMOD 2010, Ranu et al. ICDE 2015

<sup>&</sup>lt;sup>2</sup>Zang et al. MobiCom 2008, Montjoye et al. Scientific reports. 2013 < < □ > < ⊡ > < ⊡ > < ≡ > < ≡ > ○ ○

### Challenges

- Different sampling rates
  - Sampling rates of different sources can be extremely different
  - Prior work usually assumes uniform and dense sampling rates.

- 4 回 ト - 4 三 ト

#### Related Work

### Challenges

- Hard to infer the user movements from sparse trajectories
  - ► Each user only generates one GPS point every 2.63 days on average

< 回 > < 三 > < 三

### Challenges

• Data sets can be temporally disjoint

They can be collected in different time intervals

#### Related Work

### Challenges

- Trajectories of users with close relationships have significant overlaps.
  - Hard to distinguish the users in this case.

(4) (日本)

## Contribution

- Present a Mapreduce-based framework called Automatic User Identification (AUI).
- Design an effective filtering strategy for the large scale data.
- Design a novel similarity measure called **Signal Based Similarity** (SIG).
- Adopt a rejection strategy to reduce the mis-identification cases.

### Overview

Our system consists of three stages:

- Pre-processing
  - Transform each trajectory into a set of stay points
- Multi-resolution filtering
  - Partition the map with multiple resolutions
  - Select a small subset as the candidates of T<sub>A</sub>
- Verification
  - Evaluate candidates with SIG
  - Select the matching trajectories carefully

・ 何 ト ・ ヨ ト ・ ヨ ト

### Pre-processing

#### Goal: Transform each trajectory into a set of stay points

- Recall: it is hard to infer the movement due to the sparsity.
- Accumulate the GPS points during a long period (e.g. half a year)
- Extract the locations where the user stay for a while (*stay points*)
  - Denote the stay point as sp
  - sp.loc → location of stay point
  - $sp.cnt \rightarrow$  frequency of sp occurred in the data

#### Introduction

#### 2 Overview

- 3 Pre-processing
- 4 Multi-Resolution Filtering

#### 5 Verification

#### 6 Experiment

### Conclusion

Wei Cao (IIIS, at THU

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

### Multi-Resolution Filtering

Goal: Select a small subset as the candidates of trajectory  $T_A$ .

- First phase: Find the trajectories which co-occurred with  $T_A$ .
- Map stage: Input ((*T.id*, *S*))
  - Partition our map into cells with different granularities.
  - For each stay point  $sp \in S$  occurred in cell c

• Emit ((*c*, (*T.id*, *sp.cnt*))) *T.id* occurred in cell *c* for *sp.cnt* times

・ 何 ト ・ ヨ ト ・ ヨ ト

16 / 32

### Multi-Resolution Filtering

Goal: Select a small subset as the candidates of trajectory  $T_A$ .

- Reduce stage: Input ((*c*, *list*((*T*.*id*, *T*.*cnt*))))
  - ▶ For each pair  $(T_A.id \in D_A, T_B.id \in D_B)$ 
    - output(T<sub>A</sub>.id, ⟨T<sub>B</sub>.id, c, o⟩) T<sub>A</sub> co-occurred with T<sub>B</sub> in cell c for o times.

(4) (3) (4) (4) (4)

### Multi-Resolution Filtering

- Second phase: Select the candidate set of each trajectory T<sub>A</sub>
  - After the first stage, all the co-occurrences are obtained.
  - Suppose trajectory  $T_B$  co-occurred with  $T_A$  in cell c for o times
    - Add a score  $r_c \cdot o$  to  $T_B$
    - The finer granularity they co-occurred at, the larger  $r_c$  is.
  - ► For each *T<sub>A</sub>*, select the top *Q* trajectory ids with the largest scores as the candidates.

Set a large Q to ensure the actually matching trajectory is not missing.

### Signal Based Similarity

#### Description

- Take each co-occurrence as a signal.
- The signal indicates whether the trajectories belong to the same user
- Illustration:
  - Two trajectories co-occurred at home/company/station/shop
  - These co-occurrences are signals for user identification

## Signal Based Similarity

#### Description

- Distinguish observed signal and stimulus signal.
  - Initially, the "kernel cells" emits a positive stimulus signal.
  - $\blacktriangleright$  The stimulus signal spreads out with an attenuation factor  $\alpha < 1$
  - The observed signal is the superposition of decaying stimulus signals.
- Stimulus signals can better capture the mobility pattern.
- Our goal: Recover the stimulus signals from the observations.

Wei Cao (IIIS, at THU)

May 10, 2016 21 / 32

• • = • • = •

## Algorithm

(c<sub>1</sub>, o<sub>1</sub>), ..., (c<sub>m</sub>, o<sub>m</sub>): observed co-occurrences (in arbitrary order).
Calculate the observed signal in cell c<sub>k</sub>: ob(c<sub>k</sub>)

$$\mathsf{ob}(c_k;\eta,\gamma) = rac{\eta}{1+e^{-\gamma o_k}} - rac{\eta}{2}$$

• Recover the stimulus signals  $st(c_k)$  approximately:

$$\operatorname{st}(c_k) = \max \begin{cases} \operatorname{ob}(c_k) - \sum_{l < k} \operatorname{st}(c_l) \cdot \alpha^{\operatorname{Dis}_{\operatorname{grid}}(c_k, c_l)} \\ 0 \end{cases}$$

• Kernel cells:  $K = \{k : st(c_k) > 0\}$ 

## Algorithm

- We also consider the distances between kernel cells.
  - Case 1: Two stimulus signals in Tsinghua U. and Aalto U.
  - Case 2: Two stimulus signals in Tsinghua U. and Peking U.

Case 1 is more significant than case 2!

•  $md(c_k)$ : Minimal distance from cell  $c_k$  to the previous kernel cells.

• sig<sub>i</sub>: The signal at granularity *i*.

$$\operatorname{sig}_i = \operatorname{st}(c_1) + \sum_{k \in K \setminus \{1\}} \operatorname{st}(c_k) \cdot (1 + f_d(\operatorname{md}(c_k)))$$

#### $f_d()$ : sigmoid-like function

• The final signal is the combination of the signals at different granularities.

・ ロ ト ・ 同 ト ・ 三 ト ・ 三 ト

### Identification

Finally, how to identify whether there exists a matching trajectory of  $T_A$ ?

- Find  $T_B \in D_B$  with the largest signal.
- Identify whether they are matched if the signal is large enough.

To reduce misidentification, we need a stronger rejection strategy.

- Utilize Weighted Jaccard Similarity (WJS) (loffe et al ICDM) 2010.).
- $T_B$  is the matching trajectory of  $T_A$  if it has both the largest WJS and SIG score among all the candidates.

・ 同 ト ・ ヨ ト ・ ヨ ト

### Introduction

#### 2 Overview

- 3 Pre-processing

#### 5 Verification

#### 7 Conclusion

Wei Cao (IIIS, at THU

э

< □ > < □ > < □ > < □ > < □ > < □ >

Data set:

- User shared data of Baidu Inc. during 6 months (anonymized by hashing).
- Evaluate on different sampling rates:
  - Dense set: GPS location, navigation...
  - Sparse set: check-in, map queries...
- Evaluate on temporally disjoint case:
  - Part-1: aggregate the data of the first 3 months
  - Part-2: aggregate the data of the second 3 months

Setting:

- Three different data sets:
  - ► CN: 31,511 users all over China
    - $D_A = \text{CN-Dense}, D_B = \text{CN-Sparse}$
    - $D_A = \text{CN-Part1}, D_B = \text{CN-Part2}$
  - ▶ UT: 14,115 users of the same university
  - ► CB: 4,323 users of the same company

• Coverage:

- ▶ For each  $T_A \in D_A$ , find  $T_B \in D_B$  with largest similarity
- If the similarity is not large enough, reject to identify this trajectory
- Percentage of trajectories we do not reject
- Compare with existing algorithms under the same "coverage":
  - modified Hausdorff distance (Adelfio et al. EPJ Data Science 2015)
  - k-Best Connected Trajectories (Chen et al. SIGMOD 2010)

• • = • • = •

Automatic User Identification Method across

May 10, 2016 28 / 32

Performance of AUI<sup>3</sup>

- AUI combines signal based similarity and weighted jaccard similarity.
- Determines the coverage automatically according to the data set.
- Compare AUI with other methods under the same coverage.

Experiment	AUI	SIG	WJS	k-BCT	MHD
CN-Sparse vs. CN-Dense (coverage = 59.72%)	99.94%	99.84%	99.08%	98.80%	78.13%
CN-Part1 vs. CN-Part2 (coverage = 88.35%)	99.80%	99.57%	99.41%	98.20%	70.39%
CB-Sparse vs. CB-Dense (coverage = $73.31\%$ )	97.39%	97.53%	70.87%	91.59%	87.37%
CB-Part1 vs. CB-Part2 (coverage = 70.66%)	91.36%	81.67%	80.43%	65.93%	62.40%
UT-Sparse vs. UT-Dense (coverage = 72.84%)	95.63%	95.20%	76.02%	71.48%	87.32%
UT-Part1 vs. UT-Part2 (coverage = 60.81%)	90.09%	80.96%	74.97%	61.38%	50.89%

э

< □ > < □ > < □ > < □ > < □ > < □ >

### Conclusion

- Studied the user identification across heterogeneous data sources.
- Presented an algorithm which handles large scale of mobility data.
- Proposed a novel similarity for extremely noisy data.
- Adopted an effective rejection strategy.
- Conducted extensive experiments.
